

The first of these is the fact that the majority of the cases of this disease are reported from the United States and Europe. It is not known whether this is due to a higher prevalence of the disease in these countries or to a higher incidence of reporting. The second is the fact that the disease is more common in the young than in the old. This is probably due to the fact that the young are more likely to be exposed to the disease. The third is the fact that the disease is more common in the male than in the female. This is probably due to the fact that the male are more likely to be exposed to the disease.

The fourth is the fact that the disease is more common in the summer than in the winter. This is probably due to the fact that the disease is more likely to be transmitted by insects which are more active in the summer. The fifth is the fact that the disease is more common in the rural than in the urban areas. This is probably due to the fact that the rural areas are more likely to be exposed to the disease.

The sixth is the fact that the disease is more common in the South than in the North. This is probably due to the fact that the South is more likely to be exposed to the disease. The seventh is the fact that the disease is more common in the West than in the East. This is probably due to the fact that the West is more likely to be exposed to the disease.

The eighth is the fact that the disease is more common in the mountains than in the plains. This is probably due to the fact that the mountains are more likely to be exposed to the disease.
